Reporting of Noninferiority and Equivalence Randomized Trials
Extension of the CONSORT 2010 Statement

Gilda Piaggio, PhD
Diana R. Elbourne, PhD
Stuart J. Pocock, PhD
Stephen J. W. Evans, MSc
Douglas G. Altman, DSc
for the CONSORT Group

The CONSORT (Consolidated Standards of Reporting Trials) Statement, which includes a checklist and a flow diagram, is a guideline developed to help authors improve the reporting of the findings from randomized controlled trials. It was updated most recently in 2010. Its primary focus is on individually randomized trials with 2 parallel groups that assess the possible superiority of one treatment compared with another. The CONSORT Statement has been extended to other trial designs such as cluster randomization, and recommendations for noninferiority and equivalence trials were made in 2006. In this article, we present an updated extension of the CONSORT checklist for reporting noninferiority and equivalence trials, based on the 2010 version of the CONSORT Statement and the 2008 CONSORT Statement for the reporting of abstracts, and provide illustrative examples and explanations for those items that differ from the main 2010 CONSORT checklist. The intent is to improve reporting of noninferiority and equivalence trials, enabling readers to assess the reliability of their results and conclusions.

Rationale for Noninferiority or Equivalence Designs

Most RCTs aim to determine whether one intervention is superior to another. Failure to show a difference does not mean they are equivalent. By contrast, equivalence trials aim to determine whether one (typically new) intervention is therapeutically similar to another (usually an existing) treatment. We use “new” to refer to the treatment under evaluation, and the comparison or standard or reference treatment is often called an “active control.” We will generally use the term “reference treatment” for consistency.

A noninferiority trial seeks to determine whether a new treatment is not worse than a reference treatment by more than an acceptable amount.
Because proof of exact equivalence is impossible, a preselected margin of non-
inferiority (Δ) for the treatment effect in a primary patient outcome is defined. Equivalence trials are very similar, except that equivalence is defined as the treatment effect being between −Δ and +Δ. For therapeutic or prophylactic trials the noninferior-
ity approach is much more common than a true (2-sided) equivalence approach. However, equivalence trials are more common in pharmacokinet-
ics, in which a difference in either direction from the reference treatment is of importance.

Noninferiority of the new treatment with respect to the reference treatment is of interest on the premise that the new treatment has some other advantage, such as greater availability, reduced cost, less invasiveness,11,12 fewer adverse effects (harms),13 or greater ease of admin-
istration.14 In trials that investigate non-
inferiority, therefore, the question of interest is not symmetric.15 The new treatment will be recommended if it is similar to the reference treatment for a prespecified primary outcome but not if it is worse by more than Δ. Superiority of the new treatment for the primary out-
come would be an additional benefit. Some noninferiority trials have been criti-
cized for merely studying a new market-
able product (“me-too” drugs) without offering any advantages over existing products.16 The use of noninferiority or equivalence trials has been criticized on the grounds that they ask “no relevant clinical questions” and are therefore un-
ethical.17 But some observers argue that this view is misplaced.18,19

This article focuses mainly on non-
inferiority trials but applies also to the less common 2-sided equivalence trials (eAppendix, available at http://www.
jama.com).

How Common Are Noninferiority Trials?
Assessing the frequency of noninferi-
orty trials is complicated, because not all noninferiority or equivalence trials use these words, and the term “equiva-
ience” is often inappropriately used

when reporting “negative” (null) re-

sults of superiority trials; such trials often lack statistical power to rule out important differences.20,21

A recent review of 583 noninferior-
ity trials of drug therapies published between 1989 and 2009 showed an increasing trend, with only 1 trial pub-
lished before 1999 and more than 100 trials published per year from 2007.22 A third of these were in the fields of infec-
tious diseases or cardiology. An ear-
lier review found the same 2 special-
ties had the greatest number of noninferiority and equivalence trials.23 Surveys in ophthalmology24 and oncology25 also found increases in the num-
ber of such trials.

Quality of Reporting of Noninferiority Trials
Early reviews of the quality of trials claiming equivalence found that im-
portant deficiencies were common. Equivalence was inappropriately claimed in 67% of 88 studies published from 1992 to 1996 on the basis of nonsignificant tests for superior-
ity.21 Fifty-one percent stated equiva-

lence as an aim, but only 23% re-
ported that they were designed with a preset margin of equivalence. Other dis-

case- or field-specific reviews had simi-
lar findings.26-29

More recent reviews have found that the quality of reports of noninferi-
orty and equivalence trials remains poor. In one review (covering the years 1990 to 2000) only about one-
fifth of 332 noninferiority and equiva-

lence trials provided a suitable rational 
for the noninferiority margin.23 In another review covering noninferiority trials indexed in PubMed as of Febru-
ary 5, 2009, almost all of 232 published reports of equivalence and non-

feriority drug trials specified the noninferiority margin, but only 24% explained how it was determined.30-31 Other reviews had broadly similar findings.32-34 An increasing quality of reporting of noninferiority trials in oncology was observed from 2001 to 2010.35

Box. Major Changes From the 
2006 Extension of the CONSORT 
Statement for Reporting 
Noninferiority and Equivalence 
Trials

• Based on the standard CONSORT 
2010 checklist, which incorporates changes to the CONSORT 
2001 checklist described in detail in the CONSORT 2010 State-
ment9
• Uses a 2-column display to show 
more clearly the additional infor-
mation to report for noninferior-
ity trials
• New checklist for abstracts to ap-
ply to noninferiority trials
• Expanded checklist items for objec-
tives, outcomes, and interpretation
• Most examples of good reporting 
practice updated, including 10 new 
examples of good reporting from 
publications after 2006. Kept 3 ex-
amples from the 2006 extension that illustrate specific points
• Recent methodological develop-
ments are summarized in the eAp-
pendix
• Empirical evidence of reporting of 
noninferiority trials updated

Updating the CONSORT 
Statement Extension 
for Noninferiority 
Randomized Trials

The updated CONSORT 2010 State-
ment comprises a 25-item checklist and a participant flow diagram.4 In the 2010 update, some new items and sub-
items were introduced, wording was simpliﬁed and clarified, and the speciﬁc-
ity of some items was made more ex-

clicit by breaking them into sub-
items. Methodological advances 
reported in the literature since the 2001 Statement were reviewed and taken into consideration. This noninferiority ex-
tension was undertaken to reﬂect the 
updated CONSORT Statement and to integrate any significant advances in noninferiority trials methodology since 2006.
The Updating Process
An electronic search of publications citing the original CONSORT extension for noninferiority and equivalence trials was conducted using Web of Science (October 14, 2010). The search yielded 260 publications. An initial assessment of the titles and abstracts was made for relevance, yielding 142 articles. After excluding repeated publications, 137 articles remained, of which 85 were trial reports, 47 were methodological papers, and 5 were reviews of published reports of trials potentially relevant to the update of the CONSORT extension. The methodological studies and reviews were assessed for material that might influence the update. In addition, we reviewed publications from 2006 and later, including guidelines issued by both the Food and Drug Administration and the European Medicines Agency.

The revised checklist and accompanying text was distributed to other coauthors, and the subsequent revision was circulated to the larger CONSORT group for feedback. After consideration of their comments the final version was prepared and approved by the CONSORT Executive (http://www.consort-statement.org).

Methodology
Methodological considerations in noninferiority trials are discussed in the eAppendix. Key issues include the need to state the trial hypotheses in relation to the noninferiority margin; the choice of this margin; analysis using a CI approach; and the presentation and interpretation of the results using the CI in relation to the noninferiority margin (Figure 1).

Revised Extension of CONSORT Statement
To accommodate noninferiority trials, an extension of the CONSORT Statement should encompass the following main issues: (1) the rationale for adopting a noninferiority design; (2) how study hypotheses were incorporated into the design; (3) choice of participants, interventions (especially the reference treatment), and outcomes; (4) statistical methods, including sample size calculation; and (5) how the design affects interpretation and conclusions. Consequences for the CONSORT checklist, including specific changes, are described below. The flow diagram was not considered to require any specific modification.

Checklist
The revised checklist for the reporting of noninferiority trials, updated in line with the CONSORT 2010 Statement, is presented in Table 1. This checklist relates to noninferiority trials, but the same issues apply to equivalence trials.

We have reformatted the checklist in line with the style currently promoted by the CONSORT Group, as used for the extensions for nonpharmacological interventions, pragmatic trials, and cluster randomized trials. We show the text in 2 columns, the first comprising the CONSORT 2010 checklist and the second the revised extension for noninferiority trials. Several items are extended to cover reporting recommendations specific to the noninferiority design.

For each extended item, we include 1 or more examples of good reporting and

provide explanatory text. In some of the examples we have added text in brackets to explain the context. In some cases, a particular item is well reported, but providing an example does not imply that all aspects are well reported. For some items it was not possible to find a perfectly reported example. Throughout the literature, authors use different pairs of comparative terms (eg, greater than/less than, better/worse) to characterize the direction of effects, depending on whether the end points are positive (eg, survival) or negative (eg, adverse events). We have not changed the original text of each example but tried to clarify the meaning of the comparative terms used, where it might be confusing.

**Title and Abstract**

**Item 1a: Title. Standard CONSORT item**: Identification as a randomized trial in the title. *Extension for noninferiority trials*: Identification as a noninferiority randomized trial in the title.

**Example**. “Dabigatran Etxeletie Versus Enoxaparin for Prevention of Venous Thromboembolism After Total Hip Replacement: A Randomised, Double-Blind, Non-Inferiority Trial.”

**Explanation**. Readers should be able to easily identify from the title or abstract that the study was a noninferiority or equivalence randomized trial. Including the design in the title or abstract also ensures ease of identification of these studies in a literature search for inclusion in systematic reviews.

**Item 1b: Abstract. Standard CONSORT item**: Structured summary of trial design, methods, results, and conclusions (for specific guidance see CONSORT for abstracts7,8). *Extension for noninferiority trials*: See Table 2. **Example**. This example details only those parts relevant to noninferiority.43

**METHODS-OBJECTIVE**: SPECIFIC HYPOTHESIS CONCERNING NONINFERIORITY, INCLUDING NONINFERIORITY MARGIN. “To determine whether duloxetine is noninferior to (as good as) pregabalin in the treatment of pain associated with diabetic peripheral neuropathy, . . . Noninferiority would be declared if the mean improvement [in the weekly mean of the diary-based daily pain score] for duloxetine was no worse than the mean improvement for pregabalin, within statistical variability, by a margin of −0.8 unit.”

**METHODS-OBJECTIVE: CLARIFY FOR ALL REPORTED OUTCOMES WHETHER NONINFERIORITY OR SUPERIORITY.** “The primary objective was a noninferiority comparison between duloxetine and pregabalin on improvement in the weekly mean of the diary-based daily pain score (0- to 10-point scale) at end point.

“. . . adverse effects, nausea, hyperhidrosis, and decreased appetite [were secondary outcomes to be assessed for superiority].”

**RESULTS-OBJECTIVE: FOR THE PRIMARY NONINFERIORITY OUTCOME, RESULTS IN RELATION TO NONINFERIORITY MARGIN.** “The 97.5% lower confidence limit was a −0.05 difference in means, establishing noninferiority.”

**CONCLUSIONS: INTERPRETATION TAKING INTO ACCOUNT THE NONINFERIORITY HYPOTHESES AND ANY SUPERIORITY HYPOTHESES.** “Duloxetine was noninferior to pregabalin for the treatment of pain in patients with diabetic peripheral neuropathy who had an inadequate pain response to gabapentin.”

**Explanation**. Clear, transparent, and sufficiently detailed abstracts are important. Readers may only have access to the abstract, and many others skim it before deciding whether to read further. A well-written abstract also helps in retrieval of relevant reports from elec-

This checklist relates to noninferiority trials, but the same issues apply to equivalence trials. The Consolidated Standards of Reporting Trials (CONSORT) Group “strongly recommends reading this checklist in conjunction with the CONSORT 2010 Explanation and Elaboration for important clarifications on all the items.” This checklist may be republished without restriction.
tronic databases. In 2008, a CONSORT extension for reporting abstracts was published, and those recommendations were incorporated into CONSORT 2010. For noninferiority studies, the study design and the noninferiority margin are poorly reported in abstracts. In addition to the items recommended for all trials, abstracts for noninferiority RCTs should specify the noninferiority hypothesis, identify the primary outcome and noninferiority margin, and make clear whether hypotheses for other reported outcomes are noninferiority or superiority. The results should relate the primary noninferiority outcome to the noninferiority margin. The overall interpretation should take account of noninferiority and also any superiority hypotheses (Table 2).

**Introduction**

**Item 2a: Background. Standard CONSORT item:** Scientific background and explanation of rationale. **Extension for noninferiority trials:** Rationale for using a noninferiority design.

**Example.** "German guidelines consider adjuvant fluorouracil the standard of care [for locally advanced rectal cancer]. Optimisation of local tumour control has meant that distant metastases now represent the most common type of treatment failure in rectal cancer... Capecitabine is an oral fluoropyrimidine derivative that was as effective as fluorouracil plus folinic acid for adjuvant treatment of stage III colon cancer. It was also non-inferior to infusional fluorouracil in combination with oxaliplatin for first-line treatment of metastatic colorectal cancer... Capecitabine with perioperative fluorouracil in locally advanced disease. Our choice of a non-inferiority trial design was based on the expectation that non-inferiority of capecitabine, given orally on an outpatient basis, would be sufficient to tip the risk-benefit ratio in its favour."

**Explanation.** The rationale for using a noninferiority design should include evidence for the efficacy of the reference treatment in a similar context. If previous trials (preferably as part of a systematic review) demonstrated the superiority of the reference treatment relative to placebo (or an equivalent, such as "usual care" for nonpharmacological interventions) they should be cited, preferably with effect sizes and CIs. If no such trials exist, other evidence for efficacy of the reference treatment should be given. Evidence for other potential advantages of the new treatment over the reference treatment should be summarized, to justify use of the new treatment if it should be shown to be noninferior. One aim of the current trial might be to provide or support such evidence. (See also checklist items 4a, 5, and 6.)

**Item 2b: Objectives. Standard CONSORT item:** Specific objectives or hypotheses. **Extension for noninferiority trials:** Hypotheses concerning noninferiority, specifying the noninferiority margin with the rationale for its choice.

**Example.** "A sequential analysis for the antiplatelet comparison was developed and planned to first test the noninferiority of aspirin plus extended-release dipyridamole as compared with clopidogrel. If this condition was satis-

isified, then the superiority of aspirin plus extended-release dipyridamole over clopidogrel could be assessed in a second test of the conventional null hypothesis of no difference between the two treatments.

Confirmation of noninferiority in this trial involved the prespecification of a hazard ratio for aspirin plus extended-release dipyridamole, as compared with clopidogrel, that is below a predefined margin. The margin was defined in the following way. . . .”45 (See item 7a.)

Explanation. The authors should specify for which outcomes noninferiority hypotheses apply and for which superiority hypotheses apply. Usually the noninferiority hypothesis refers to the primary end point, whereas the new treatment is expected to offer other advantages, eg, fewer adverse effects or lower cost. If the trial is multigroup or the treatments have a factorial structure, the comparisons to which the noninferiority hypothesis applies should be specified. If sequential testing of noninferiority and superiority hypotheses was planned, that should also be reported.

The rationale for the choice of the noninferiority margin and whether the margin is based on a relative or absolute scale should be specified because relative measures tend to make it less easy to conclude noninferiority, particularly when observed rates turn out to be smaller than the expected rates.46,47

The method used to set the margin of noninferiority should be reported. Conventionally, the margin is taken as the size of the effect considered clinically irrelevant. That approach might show an ineffective new treatment as noninferior if the margin is too large in relation to the effect of the reference treatment compared with placebo. To prove that the new treatment is effective, the effect retention or putative placebo method has been proposed (eAppendix),36 and it should be used if possible if the noninferiority trial is aimed for drug approval.35,47

METHODS

Item 4a: Participants. Standard CONSORT item: Eligibility criteria for participants. Extension for noninferiority trials: Whether participants in the noninferiority trial are similar to those in any trial(s) that established efficacy of the reference treatment.

Example. “[We] enrolled 6628 men and women in 312 health centres in Sweden . . . who had hypertension (blood pressure ≥180 mm Hg systolic, ≥105 mm Hg diastolic, or both), aged 70–84 years. The only difference in inclusion criteria between this trial and the STOP-Hypertension trial was that patients with isolated systolic hypertension could be included in STOP Hypertension–2, based on previous positive findings in patients with isolated systolic hypertension treated with diuretics and calcium antagonists.”48

Explanation. Because an inference of noninferiority relies on evidence that the reference treatment is effective (see “Assay Sensitivity” in eAppendix), relevant differences in participants’ characteristics compared with previous trials should be reported and explained. Such description should concentrate on differences that might affect response to treatments. For continuous variables it is important to provide not just the mean values but also an indication of variability (eg, standard deviation).

Item 5: Interventions. Standard CONSORT item: The interventions for each group with sufficient details to allow replication, including how and when they were actually administered. Extension for noninferiority trials: Whether the reference treatment in the noninferiority trial is identical (or very similar) to that in any trial(s) that established efficacy.

Example. “[S]even large, randomised, placebo-controlled trials involving a total of 16,770 patients who underwent percutaneous interventions have established that the overall reduction in the risk of death or nonfatal myocardial infarction 30 days after adjunctive inhibition of platelet glycoprotein IIb/IIa receptors is 38 percent [relative reduction]. . . . The primary end point [in the present trial] was a composite of death, nonfatal myocardial infarction, or urgent target-vessel revascularization within 30 days after the index procedure.”51

Explanation. Any differences in outcome measures in the new trial compared with trials that established efficacy of the reference treatment should be noted and explained. In particular,
authors should note any differences in the timing of evaluation. Ideally, outcomes should not be changed, but changes may be indicated by improvements in the understanding, management, and prognosis of a disease. For example, early acquired immunodeficiency syndrome (AIDS) trials had death as the primary outcome, but as deaths became uncommon, the focus shifted to AIDS clinical events, then shifted again to surrogate markers as clinical events became uncommon.

**Item 7a: Sample Size.** *Standard CONSORT item: How sample size was determined.* *Extension for noninferiority trials:* Whether the sample size was calculated using a noninferiority criterion and, if so, what the noninferiority margin was.

**Example 1 (noninferiority).** “Using data from the nonfatal stroke outcomes from the Clopidogrel versus Aspirin in Patients at Risk of Ischemic Events trial and from the meta-analysis by the Antithrombotic Trialists’ Collaboration . . . , we derived an estimated odds ratio for clopidogrel being better than placebo for the outcome of nonfatal stroke: 1.377 (95% confidence interval [CI], 1.155 to 1.645). Thus, to ensure that the aspirin plus extended-release dipyridamole preserved at least half the effect of clopidogrel, the noninferiority margin was set at 1.075, an effect size equal to half the lower limit of the confidence interval. . . . With 1715 recurrent strokes, we would have a statistical power of 82% to reject the inferiority null hypothesis, assuming a 6.5% relative risk reduction with aspirin plus extended-release dipyridamole as compared with clopidogrel.”

**Example 2 (equivalence).** “The margin of equivalence, , was 5% and the range −5% to 5% was predefined as an acceptable range of completion rates [of medical abortion] between the two types of providers. The margin was based on clinically and statistically important differences as well as ethical criteria, cost, and feasibility. The sample size of 1086 women was calculated to be sufficient (with a two-sided 95% CI and 80% power) to establish equivalence. The sample size calculation allowed for 10% loss to follow-up . . . .”

**Explanation.** The margin of noninferiority should be specified and preferably justified on clinical grounds. If is too large, there will be too great a risk of accepting a truly inferior treatment as noninferior. This concern is especially relevant for serious outcomes such as mortality. On the other hand, defining a very small might produce inconclusive results, requiring an extremely large trial if adequate power is to be achieved. If is chosen to be a proportion of the difference between reference treatment and placebo in previous trials (ratio approach), that should be noted.

**Item 7b: Interim analyses and stopping guidelines.** *Standard CONSORT item: When applicable, explanation of any interim analyses and stopping guidelines.* *Extension for noninferiority trials:* To which outcome(s) they apply and whether related to a noninferiority hypothesis.

**Example [noninferiority trial with stopping criterion based on superiority].** “A data and safety monitoring board reviewed the data periodically for safety and efficacy. They could recommend stopping the study if a benefit in favour of oral anticoagulation therapy was shown, such that the hazard ratio for clopidogrel plus aspirin versus oral anticoagulation therapy exceeded 1.0 by more than 3 SD at either of two formal interim analyses, timed to occur when 50% or 75% of events had occurred. . . .”

**Explanation.** In superiority trials, if an interim analysis shows clear evidence of the efficacy of the new treatment, it may be considered unethical to continue the trial and deny the new effective treatment to the control group. In contrast, in noninferiority trials, if noninferiority is demonstrated for the primary outcome (using the prestated noninferiority margin) before completion of the trial, there is less ethical need to stop the trial because the control group is already receiving the standard treatment and the experimental treatment is not appearing appreciably worse. Also, if noninferiority is evident at interim analysis and the point estimate is favorable, the investigators or the data monitoring committee may then wish to continue in the hope of demonstrating superiority. In noninferiority trials it is therefore often more appropriate to base stopping rules on safety outcomes and superiority hypotheses. Stopping rules for efficacy in noninferiority trials may be asymmetric, i.e., may favor stopping early if the new treatment is appearing worse than the standard but continuing longer if the new treatment is appearing better. Formal stopping rules for futility may be particularly important for noninferiority trials (given that the comparison is with a proven standard therapy). It has been suggested that relating the observed effect to the point of “no effect” rather than the noninferiority margin may be more appropriate for considering futility and harm in noninferiority trials and that “the data would have to show convincing evidence of harm before the trial would be stopped for futility.”

**Item 12a: Statistical Methods.** *Standard CONSORT item: Statistical methods used to compare groups for primary and secondary outcomes.* *Extension for noninferiority trials:* Whether a 1- or 2-sided confidence interval approach was used.

**Example 1 (noninferiority, continuous outcome).** “The primary efficacy endpoint was the mean change in pain intensity. . . . Study endpoints were analysed primarily for the per protocol population.
and repeated, for sensitivity reasons, for the intention-to-treat (ITT) population. For most efficacy endpoints, a confidence interval (CI) approach was used on an analysis of covariance (ANCOVA) model, with a two-sided 5% level of significance. For the primary efficacy endpoint, non-inferiority of lumiracoxib to indomethacin could be claimed if the lower limit of the CI [for the difference in mean change of pain intensity assessed on a 5-point Likert scale] was greater than -0.5. This test for non-inferiority was only performed for the primary efficacy variable; all other secondary variables were tests of superiority of lumiracoxib versus indomethacin.  

Example 2 (noninferiority, binary outcome). The trial was powered for separate comparisons between the control group [unfractionated heparin or enoxaparin plus a glycoprotein IIb/IIIa inhibitor] and each of the two investigational groups. We used sequential noninferiority and superiority analyses with hierarchical end-point testing, with the type 1 error controlled by the Benjamini and Hochberg procedure, as previously described. Noninferiority was declared if the upper limit of the one-sided 97.5% confidence interval (CI) for the event rate in the investigational group did not exceed a relative margin of 25% from the event rate in the control group [risk ratio = 1.25], equivalent to a one-sided test with an alpha value of 0.025. A two-sided alpha value of 0.05 was used for superiority testing.  

Example 3 (equivalence, binary outcome). To assess the equivalence between midlevel healthcare providers and doctors, the risk difference between the two provider types together with their [two-sided] 95% CI was derived by use of a generalised estimating equation (GEE) model. [The primary endpoint was complete abortion] ... If the CI of the risk difference between the two groups falls within the predetermined margin of equivalence (-5% to 5%), the two types of providers can be considered equivalent. The analyses for the primary and secondary endpoints were on an intention-to-treat basis, supplemented by per-protocol analysis of the primary endpoint.  

Explanation. Tests of noninferiority need to be related to the $\Delta$ and $\alpha$ as pre-specified in the noninferiority hypothesis. It should be specified whether an absolute difference between treatments or a relative measure, or both, will be used. Judgment of the results in relation to the study hypothesis is based on the location of the whole CI in relation to $\Delta$ (Figure 1). For noninferiority trials, the upper bound of the 2-sided $(1 - 2\alpha) \times 100\%$ CI for the (deleterious) treatment effect or the upper bound of the 1-sided $(1 - \alpha) \times 100\%$ CI has to be below the margin $\Delta$ to declare that noninferiority has been shown, with a significance level $\alpha$. The 2-sided CI provides additional information, in particular for the situation in which the new treatment is superior to the reference treatment. For equivalence trials, equivalence is demonstrated if the entire 2-sided $(1 - \alpha) \times 100\%$ CI lies within $-\Delta$ and $\Delta$. If noninferiority has been demonstrated, it is then acceptable to assess whether the new treatment appears superior to the reference treatment, using an appropriate test or CI, with a significance level or confidence, respectively, defined a priori in the protocol and with an ITT analysis. Conversely, occasionally a trial protocol may specify that if superiority is not demonstrated, a noninferiority analysis will be performed. Such sequential testing should be fully explained.  

Results  

Item 17a: Outcomes and Estimation. Standard CONSORT item: For each primary and secondary outcome, results for each group, the estimated effect size and its precision (such as 95% CI). Extension for noninferiority trials: For the outcome(s) for which noninferiority was hypothesized, a figure showing CIs and the noninferiority margin may be useful.  

Example (noninferiority of new treatment). The unadjusted HR comparing overall survival between the SLND [sentinel lymph node dissection]-alone group and the ALND [axillary lymph node dissection] group was 0.79 (90% CI, 0.56-1.10), which did not cross the specified boundary of 1.3. The HR for overall survival adjusting for adjuvant therapy ... and age for the SLND-alone group compared with the ALND group was 0.87 (90% CI, 0.62-1.23) (Figure 2).  

Explanation. A figure helps readers to interpret the result based on the CI, because it shows graphically where the CI lies with respect to the null value (if a risk difference is used) or to 1 (if a relative measure is used) and with respect to the margin of noninferiority or the margins of equivalence. In the example the new treatment was noninferior. The figure can be used to show graphically the results of different analyses, eg, with or without adjustment (Figure 2) or ITT and per protocol.  

Only 1 of 47 published equivalence or noninferiority trials in ophthalmology evaluating prostaglandins depicted the CI graphically with the prespecified noninferiority or equivalence margin.  

Discussion  

Item 22: Interpretation. Standard CONSORT item: Interpretation consistent with results, balancing benefits and harms, and considering other relevant evidence. Extension for noninferiority trials: Interpret results in relation to the noninferiority hypothesis. If a superi-
priority conclusion is drawn for outcome(s) for which noninferiority was hypothesized, provide justification for switching.

Example 1 (concluding inferiority of new drug or conventional superiority of reference drug). “Although the trial was intended to assess the non-inferiority of tirofiban as compared with abciximab, the findings demonstrated that tirofiban offered less protection from major ischemic events than did abciximab. . . In order to meet the present definition of equivalence, the upper bound of the 95% confidence interval of the hazard ratio for the comparison of tirofiban with abciximab had to be less than 1.47. . . . The primary endpoint occurred more frequently among the 2398 patients in the tirofiban group than among the 2411 patients in the abciximab group (7.6 percent vs 6.0 percent; hazard ratio, 1.26; . . . two-sided 95% confidence interval of 1.01 to 1.57, demonstrating the superiority of abciximab over tirofiban; P = 0.038).”

Example 2 (concluding noninferiority of new drug from a trial designed to assess superiority). “The SYNERGY protocol prespecified that if enoxaparin was not demonstrated to be superior to unfractionated heparin, a non-inferiority analysis was to be performed. . . Enoxaparin was not superior to unfractionated heparin but was noninferior for the treatment of high-risk patients with non ST-segment elevation [acute coronary syndromes].”

Example 3 (concluding equivalence). “The risk difference for complete abortion was 1.24% (95% CI −0.53 to 3.02), which falls within the predefined equivalence range (−5% to 5%). . . . The provision of medical abortion up to 9 weeks’ gestation by midlevel providers and doctors was similar in . . . effectiveness.”

Explanation. The results of any trial must be interpreted in relation to its aims. As shown in Figure 1, assuming an adverse outcome calculated as new vs reference, if the upper bound of the 2-sided (1 − 2α) × 100% CI for the difference between treatments is below Δ, noninferiority may be claimed. Alternative explanations such as poor adherence, dropouts, recruitment of patients unlikely to respond, and treatment crossovers may need to be considered (see “Conduct” in eAppendix). If instead the upper bound is above the noninferiority margin Δ, the null hypothesis of inferiority remains plausible. If the 2-sided CI for the treatment difference is entirely to the left of zero as in case A of Figure 1, then it can be sensibly concluded that there is statistically significant evidence that the new treatment is superior to reference, if the superiority hypothesis is defined a priori in the protocol and the analysis is ITT. It should be indicated whether the conclusion relating to noninferiority or equivalence is based on ITT or per-protocol analysis or both and whether those conclusions are stable with respect to different types of analyses (eg, ITT, per-protocol). Conclusions should preferably be stated in terms of the prespecified noninferiority or equivalence margin using language consistent with the aim of the trial (eg, treatment A is “noninferior to” or “equivalent to” treatment B).

COMMENT

Available efficacious active treatments can make use of placebo controls unethical. Noninferiority trials, comparing a new treatment with a standard, are becoming frequent because of the need to replace standard treatments by other treatments having comparable efficacy but presenting other advantages. Even in cases for which a treatment is efficacious on some measures, eg, depression scales, it may not be efficacious for a rarer but arguably more important outcome, eg, suicide.

It is not our intent to promote noninferiority or equivalence trials but to contribute to better reporting and understanding of these trials: the design of a trial should be appropriate to the question to be answered. Reports of noninferiority and equivalence trials must be clear enough to allow readers to interpret results reliably. Accordingly, we have provided an updated extension to the CONSORT Statement to facilitate appropriate reporting of noninferiority and equivalence trials.

The present recommendations are among a series of extensions to the CONSORT Statement. The current versions of all CONSORT recommendations are available at http://www.consort-statement.org.

Author Contributions: Dr Piaggio had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study concept and design: Piaggio, Elbourne, Pocock, Evans, Altman.

Acquisition of data: Piaggio, Elbourne, Altman.

Analysis and interpretation of data: Piaggio, Elbourne, Altman.

Drafting of the manuscript: Piaggio, Elbourne, Pocock, Altman.

Critical revision of the manuscript for important intellectual content: Piaggio, Pocock, Evans, Altman.

Obtained funding: Altman.

Conflict of Interest Disclosures: All authors have completed and submitted the ICMJE Form for Disclosure of Potential Conflicts of Interest and none were reported.

Funding/Support: The CONSORT Group receives funding from the UK Medical Research Council. Dr Piaggio and Dr Elbourne received a small contribution from the CONSORT group toward the time spent on this and other CONSORT work. Dr Piaggio was supported by the CONSORT group to attend meetings in London. Dr Altman is supported by a Cancer Research UK programme grant (C5529).

Role of the Sponsors: The study sponsors had no role in the design and conduct of the study; the collection, management, analysis, and interpretation of the data; or the preparation, review, or approval of the manuscript.

Additional Contributions: We thank the members of the CONSORT Group for comments on earlier drafts. This group endorsed the submission for publication.
